

MATRIX ISOLATION AS A TOOL FOR STUDYING
INTERSTELLAR CHEMICAL REACTIONS

David W. Ball, Bryan J. Ortman, Robert H. Hauge, John L. Margrave,
Department of Chemistry, Rice University, Houston, Texas, 77251

Since the identification of the OH radical as an interstellar species (Barrett and Lilly, 1957), over 50 molecular species have been identified as interstellar denizens. While identification of new species appears straightforward, an explanation for their mechanisms of formation is not. While most astronomers concede that "large" bodies like interstellar dust grains are necessary for adsorption of molecules and their energies of reactions (Watson and Salpeter, 1972; Allen and Robinson, 1975), many of the mechanistic steps are unknown and speculative.

We propose that data from matrix isolation experiments involving the reactions of refractory materials (especially C, Si, and Fe atoms and clusters) with small molecules (mainly H₂, H₂O, CO, CO₂, and O₂) are particularly applicable to explaining mechanistic details of likely interstellar chemical reactions. In many cases, matrix isolation techniques are the sole method of studying such reactions; also in many cases, complexations and bond rearrangements yield molecules never before observed. The study of these reactions thus provides a logical basis for the mechanisms of interstellar reactions.

Table 1 shows a list of reactions studied in our laboratory that would simulate interstellar chemical reactions. These reactions were studied using FTIR-matrix isolation techniques. This Table does not represent an exhaustive list of reactions studied; we only include reactions of species having astronomical interest. We do point out, however, that the preponderance of reactive pathways shown here hints that true interstellar space is certainly a "soup" of chemical species, about which much is still unknown.
